

ABSTRACT OF THE DISCLOSURE

An information input apparatus and method is provided, by which newly shot images can be recorded in an electronic camera or other device, while other images are being displayed. If a specified image is shot while an image that is recorded in memory is being displayed on display mode, the image that is shot is overwritten from an address in a area in which the image which is being displayed is recorded. On the other hand, when a specified image is shot in recording mode, the image that is shot is added from an address in an unrecorded area of the memory card to which no images have been recorded.
